Environmental Audit Notes – Reference Page 1

During the operational review, the engineering team documented changes in bearing temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 2

During the operational review, the engineering team documented changes in motor current associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Consumption Reports – Reference Page 3

During the operational review, the engineering team documented changes in pressure associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased feed rate observed in Clinker Cooler during routine monitoring.	Process imbalance	Kiln instability risk	Inspect equipment immediately
Increased power consumption observed in Clinker Cooler during routine monitoring.	Improper lubrication	Quality fluctuation risk	Adjust process parameters
Increased pressure observed in Limestone Crusher during routine monitoring.	Improper lubrication	Quality fluctuation risk	Schedule maintenance shutdown
Increased motor current observed in Packing Machine	Dust accumulation	Kiln instability risk	Adjust process parameters

during routine monitoring.			
Increased vibration observed in Limestone Crusher during routine monitoring.	Bearing wear	Kiln instability risk	Adjust process parameters

Shutdown and Turnaround Reports – Reference Page 4

During the operational review, the engineering team documented changes in pressure associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Root Cause Analysis Records – Reference Page 5

During the operational review, the engineering team documented changes in power consumption associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	8% higher than last week	Possible process fluctuation
Raw Mill	Energy optimization required	Investigate equipment load
Cement Grinding	Within target range	Possible process fluctuation
Packing Plant	8% higher than last week	Investigate equipment load
Utilities	Within target range	Possible process fluctuation

Equipment Failure Case Studies – Reference Page 6

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased bearing temperature observed in Electrostatic Precipitator during routine monitoring.	Improper lubrication	Higher energy consumption	Adjust process parameters
Increased pressure observed in Cement Separator during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Conduct vibration analysis
Increased motor current observed in Clinker Cooler during routine monitoring.	Bearing wear	Quality fluctuation risk	Conduct vibration analysis
Increased bearing temperature observed in Packing	Operator parameter adjustment	Kiln instability risk	Conduct vibration analysis

Machine during routine monitoring.			
Increased motor current observed in Bucket Elevator during routine monitoring.	Process imbalance	Reduced mill throughput	Inspect equipment immediately

Kiln Performance Analysis – Reference Page 7

During the operational review, the engineering team documented changes in feed rate associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Operational Incident Reports – Reference Page 8

During the operational review, the engineering team documented changes in pressure associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 9

During the operational review, the engineering team documented changes in temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased vibration observed in Cement Separator during routine monitoring.	Bearing wear	Reduced mill throughput	Adjust process parameters
Increased feed rate observed in Clinker Cooler during routine monitoring.	Improper lubrication	Higher energy consumption	Conduct vibration analysis
Increased bearing temperature observed in Bucket Elevator during routine monitoring.	Dust accumulation	Quality fluctuation risk	Inspect equipment immediately
Increased motor current observed in Electrostatic Precipitator during	Process imbalance	Kiln instability risk	Schedule maintenance shutdown

routine monitoring.

Increased bearing temperature observed in Cement Separator during routine monitoring.	Improper lubrication	Reduced mill throughput	Adjust process parameters

Kiln Performance Analysis – Reference Page 10

During the operational review, the engineering team documented changes in power consumption associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	5% above baseline	Possible process fluctuation
Raw Mill	8% higher than last week	Investigate equipment load
Cement Grinding	Energy optimization required	Investigate equipment load
Packing Plant	8% higher than last week	Possible process fluctuation
Utilities	5% above baseline	Possible process fluctuation

Environmental Audit Notes – Reference Page 11

During the operational review, the engineering team documented changes in motor current associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 12

During the operational review, the engineering team documented changes in feed rate associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. During the operational review, the engineering team documented changes in power consumption associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased temperature observed in Rotary Kiln during routine monitoring.	Improper lubrication	Kiln instability risk	Adjust process parameters
Increased pressure observed in ID Fan during routine monitoring.	Bearing wear	Quality fluctuation risk	Conduct vibration analysis
Increased air flow observed in Vertical Roller Mill during routine monitoring.	Bearing wear	Higher energy consumption	Adjust process parameters
Increased air flow observed in Bucket Elevator during routine monitoring.	Process imbalance	Kiln instability risk	Adjust process parameters

Increased air flow observed in Limestone Crusher during routine monitoring.	Dust accumulation	Kiln instability risk	Schedule maintenance shutdown

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Energy optimization required	Monitor for next shift
Raw Mill	5% above baseline	Investigate equipment load
Cement Grinding	Within target range	Monitor for next shift
Packing Plant	Energy optimization required	Possible process fluctuation
Utilities	Within target range	Investigate equipment load

Maintenance Work Orders – Reference Page 31

During the operational review, the engineering team documented changes in motor current associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Investigation Reports – Reference Page 32

During the operational review, the engineering team documented changes in temperature associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 33

During the operational review, the engineering team documented changes in air flow associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased temperature observed in Electrostatic Precipitator during routine monitoring.	Improper lubrication	Reduced mill throughput	Inspect equipment immediately
Increased air flow observed in Bucket Elevator during routine monitoring.	Dust accumulation	Kiln instability risk	Adjust process parameters
Increased vibration observed in ID Fan during routine monitoring.	Bearing wear	Higher energy consumption	Inspect equipment immediately
Increased temperature observed in Raw Mill	Dust accumulation	Quality fluctuation risk	Conduct vibration analysis

Fan during routine monitoring.			
Increased power consumption observed in Vertical Roller Mill during routine monitoring.	Dust accumulation	Reduced mill throughput	Inspect equipment immediately

Environmental Audit Notes – Reference Page 34

During the operational review, the engineering team documented changes in power consumption associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Root Cause Analysis Records – Reference Page 35

During the operational review, the engineering team documented changes in power consumption associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	5% above baseline	Investigate equipment load
Raw Mill	5% above baseline	Investigate equipment load
Cement Grinding	Energy optimization required	Possible process fluctuation
Packing Plant	8% higher than last week	Engineering team notified
Utilities	Energy optimization required	Investigate equipment load

Process Optimization Notes – Reference Page 36

During the operational review, the engineering team documented changes in pressure associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Cement Separator during routine monitoring.	Bearing wear	Reduced mill throughput	Inspect equipment immediately
Increased feed rate observed in Ball Mill during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Adjust process parameters
Increased air flow observed in Bag Filter during routine monitoring.	Dust accumulation	Quality fluctuation risk	Schedule maintenance shutdown
Increased power consumption observed in Raw Mill Fan during routine monitoring.	Process imbalance	Reduced mill throughput	Adjust process parameters

Increased bearing temperature observed in Rotary Kiln during routine monitoring.	Bearing wear	Kiln instability risk	Schedule maintenance shutdown

Production Planning Notes – Reference Page 37

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Investigation Reports – Reference Page 38

During the operational review, the engineering team documented changes in temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Equipment Failure Case Studies – Reference Page 39

During the operational review, the engineering team documented changes in motor current associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased pressure observed in Electrostatic Precipitator during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Conduct vibration analysis
Increased temperature observed in Bucket Elevator during routine monitoring.	Process imbalance	Reduced mill throughput	Conduct vibration analysis
Increased bearing temperature observed in Clinker Cooler during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Adjust process parameters
Increased temperature	Bearing wear	Quality fluctuation risk	Schedule maintenance

observed in Rotary Kiln during routine monitoring.			shutdown
Increased air flow observed in Clinker Cooler during routine monitoring.	Dust accumulation	Higher energy consumption	Adjust process parameters

Root Cause Analysis Records – Reference Page 40

During the operational review, the engineering team documented changes in bearing temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Energy optimization required	Monitor for next shift
Raw Mill	Energy optimization required	Engineering team notified
Cement Grinding	5% above baseline	Engineering team notified
Packing Plant	Energy optimization required	Monitor for next shift
Utilities	Within target range	Engineering team notified

Operational Incident Reports – Reference Page 41

During the operational review, the engineering team documented changes in motor current associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Maintenance Work Orders – Reference Page 42

During the operational review, the engineering team documented changes in bearing temperature associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. During the operational review, the engineering team documented changes in vibration associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Environmental Audit Notes – Reference Page 60

During the operational review, the engineering team documented changes in motor current associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased power consumption observed in Bag Filter during routine monitoring.	Bearing wear	Reduced mill throughput	Schedule maintenance shutdown
Increased motor current observed in Electrostatic Precipitator during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Schedule maintenance shutdown
Increased temperature observed in Bag Filter during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Inspect equipment immediately
Increased power consumption	Improper lubrication	Quality fluctuation risk	Inspect equipment immediately

observed in Raw Mill Fan during routine monitoring.			
Increased motor current observed in Packing Machine during routine monitoring.	Bearing wear	Quality fluctuation risk	Schedule maintenance shutdown

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	8% higher than last week	Investigate equipment load
Raw Mill	Energy optimization required	Possible process fluctuation
Cement Grinding	Within target range	Engineering team notified
Packing Plant	5% above baseline	Investigate equipment load
Utilities	Energy optimization required	Possible process fluctuation

Environmental Audit Notes – Reference Page 61

During the operational review, the engineering team documented changes in feed rate associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Shutdown and Turnaround Reports – Reference Page 62

During the operational review, the engineering team documented changes in feed rate associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Kiln Performance Analysis – Reference Page 63

During the operational review, the engineering team documented changes in pressure associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Packing Machine during routine monitoring.	Dust accumulation	Kiln instability risk	Inspect equipment immediately
Increased temperature observed in Electrostatic Precipitator during routine monitoring.	Bearing wear	Higher energy consumption	Conduct vibration analysis
Increased air flow observed in Raw Mill Fan during routine monitoring.	Process imbalance	Reduced mill throughput	Schedule maintenance shutdown
Increased bearing temperature observed in Rotary	Operator parameter adjustment	Quality fluctuation risk	Conduct vibration analysis

Kiln during routine monitoring.			
Increased power consumption observed in Bucket Elevator during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Conduct vibration analysis

Quality Deviation Reports – Reference Page 64

During the operational review, the engineering team documented changes in pressure associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Equipment Failure Case Studies – Reference Page 65

During the operational review, the engineering team documented changes in vibration associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Energy optimization required	Investigate equipment load
Raw Mill	5% above baseline	Engineering team notified
Cement Grinding	8% higher than last week	Monitor for next shift
Packing Plant	Within target range	Possible process fluctuation
Utilities	Within target range	Monitor for next shift

Process Optimization Notes – Reference Page 66

During the operational review, the engineering team documented changes in motor current associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased bearing temperature observed in Rotary Kiln during routine monitoring.	Bearing wear	Higher energy consumption	Adjust process parameters
Increased vibration observed in Vertical Roller Mill during routine monitoring.	Improper lubrication	Quality fluctuation risk	Conduct vibration analysis
Increased vibration observed in Cement Separator during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Adjust process parameters
Increased temperature observed in Clinker Cooler during routine	Bearing wear	Reduced mill throughput	Schedule maintenance shutdown

monitoring.

Increased air flow observed in ID Fan during routine monitoring.	Bearing wear	Higher energy consumption	Schedule maintenance shutdown

Equipment Failure Case Studies – Reference Page 67

During the operational review, the engineering team documented changes in vibration associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Root Cause Analysis Records – Reference Page 68

During the operational review, the engineering team documented changes in feed rate associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Maintenance Work Orders – Reference Page 69

During the operational review, the engineering team documented changes in feed rate associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Rotary Kiln during routine monitoring.	Bearing wear	Reduced mill throughput	Schedule maintenance shutdown
Increased pressure observed in Cement Separator during routine monitoring.	Improper lubrication	Quality fluctuation risk	Conduct vibration analysis
Increased vibration observed in Bag Filter during routine monitoring.	Bearing wear	Quality fluctuation risk	Conduct vibration analysis
Increased bearing temperature observed in Raw Mill Fan during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Conduct vibration analysis

Increased power consumption observed in Vertical Roller Mill during routine monitoring.	Process imbalance	Kiln instability risk	Schedule maintenance shutdown

Root Cause Analysis Records – Reference Page 70

During the operational review, the engineering team documented changes in temperature associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Within target range	Monitor for next shift
Raw Mill	Within target range	Engineering team notified
Cement Grinding	Within target range	Investigate equipment load
Packing Plant	Within target range	Investigate equipment load
Utilities	Energy optimization required	Monitor for next shift

Production Planning Notes – Reference Page 71

During the operational review, the engineering team documented changes in vibration associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Kiln Performance Analysis – Reference Page 72

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased motor current observed in Packing Machine during routine monitoring.	Dust accumulation	Quality fluctuation risk	Schedule maintenance shutdown
Increased motor current observed in Electrostatic Precipitator during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Inspect equipment immediately
Increased feed rate observed in Cement Separator during routine monitoring.	Improper lubrication	Higher energy consumption	Schedule maintenance shutdown
Increased bearing temperature observed in Bucket	Operator parameter adjustment	Kiln instability risk	Adjust process parameters

Elevator during routine monitoring.			
Increased feed rate observed in Cement Separator during routine monitoring.	Process imbalance	Higher energy consumption	Schedule maintenance shutdown

Quality Deviation Reports – Reference Page 88

During the operational review, the engineering team documented changes in motor current associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Production Planning Notes – Reference Page 89

During the operational review, the engineering team documented changes in air flow associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Shutdown and Turnaround Reports – Reference Page 90

During the operational review, the engineering team documented changes in temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Bucket Elevator during routine monitoring.	Bearing wear	Kiln instability risk	Conduct vibration analysis
Increased temperature observed in ID Fan during routine monitoring.	Dust accumulation	Kiln instability risk	Inspect equipment immediately
Increased bearing temperature observed in Cement Separator during routine monitoring.	Dust accumulation	Kiln instability risk	Adjust process parameters
Increased pressure observed in Bucket Elevator during	Improper lubrication	Reduced mill throughput	Inspect equipment immediately

routine monitoring.

Increased power consumption observed in Bag Filter during routine monitoring.	Process imbalance	Higher energy consumption	Inspect equipment immediately

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	8% higher than last week	Engineering team notified
Raw Mill	Energy optimization required	Investigate equipment load
Cement Grinding	Within target range	Possible process fluctuation
Packing Plant	8% higher than last week	Possible process fluctuation
Utilities	5% above baseline	Monitor for next shift

Production Planning Notes – Reference Page 91

During the operational review, the engineering team documented changes in vibration associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 92

During the operational review, the engineering team documented changes in motor current associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Production Planning Notes – Reference Page 93

During the operational review, the engineering team documented changes in temperature associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Bag Filter during routine monitoring.	Process imbalance	Quality fluctuation risk	Conduct vibration analysis
Increased motor current observed in ID Fan during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Adjust process parameters
Increased power consumption observed in Electrostatic Precipitator during routine monitoring.	Bearing wear	Reduced mill throughput	Inspect equipment immediately
Increased vibration observed in ID Fan during routine	Process imbalance	Quality fluctuation risk	Adjust process parameters

monitoring.			
Increased vibration observed in Clinker Cooler during routine monitoring.	Dust accumulation	Kiln instability risk	Inspect equipment immediately

Kiln Performance Analysis – Reference Page 94

During the operational review, the engineering team documented changes in pressure associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Equipment Failure Case Studies – Reference Page 95

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	8% higher than last week	Monitor for next shift
Raw Mill	8% higher than last week	Monitor for next shift
Cement Grinding	Within target range	Investigate equipment load
Packing Plant	5% above baseline	Possible process fluctuation
Utilities	Energy optimization required	Monitor for next shift

Kiln Performance Analysis – Reference Page 96

During the operational review, the engineering team documented changes in pressure associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased bearing temperature observed in Ball Mill during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Adjust process parameters
Increased vibration observed in Packing Machine during routine monitoring.	Dust accumulation	Kiln instability risk	Schedule maintenance shutdown
Increased motor current observed in Vertical Roller Mill during routine monitoring.	Process imbalance	Quality fluctuation risk	Conduct vibration analysis
Increased pressure observed in Electrostatic	Operator parameter adjustment	Higher energy consumption	Schedule maintenance shutdown

Precipitator during routine monitoring.			
Increased air flow observed in Bag Filter during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Adjust process parameters

Operational Incident Reports – Reference Page 97

During the operational review, the engineering team documented changes in pressure associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Production Planning Notes – Reference Page 98

During the operational review, the engineering team documented changes in pressure associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Improvement Recommendations – Reference Page 99

During the operational review, the engineering team documented changes in bearing temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased pressure observed in Bucket Elevator during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Adjust process parameters
Increased bearing temperature observed in Bucket Elevator during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Inspect equipment immediately

Process Optimization Notes – Reference Page 117

During the operational review, the engineering team documented changes in temperature associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased bearing temperature observed in Cement Separator during routine monitoring.	Dust accumulation	Higher energy consumption	Inspect equipment immediately
Increased vibration observed in Raw Mill Fan during routine monitoring.	Bearing wear	Kiln instability risk	Schedule maintenance shutdown
Increased feed rate observed in Electrostatic Precipitator during routine monitoring.	Improper lubrication	Higher energy consumption	Adjust process parameters
Increased air flow observed in Limestone Crusher	Operator parameter adjustment	Reduced mill throughput	Inspect equipment immediately

during routine monitoring.			
Increased feed rate observed in Electrostatic Precipitator during routine monitoring.	Bearing wear	Quality fluctuation risk	Conduct vibration analysis

Engineering Investigation Reports – Reference Page 118

During the operational review, the engineering team documented changes in air flow associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Optimization Notes – Reference Page 119

During the operational review, the engineering team documented changes in motor current associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Equipment Failure Case Studies – Reference Page 120

During the operational review, the engineering team documented changes in bearing temperature associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased vibration observed in Clinker Cooler during routine monitoring.	Bearing wear	Kiln instability risk	Schedule maintenance shutdown
Increased feed rate observed in Bucket Elevator during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Adjust process parameters
Increased air flow observed in Clinker Cooler during routine monitoring.	Dust accumulation	Quality fluctuation risk	Inspect equipment immediately
Increased feed rate observed in Raw Mill Fan during routine monitoring.	Bearing wear	Quality fluctuation risk	Schedule maintenance shutdown

Increased feed rate observed in Raw Mill Fan during routine monitoring.	Bearing wear	Kiln instability risk	Adjust process parameters

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	8% higher than last week	Monitor for next shift
Raw Mill	8% higher than last week	Monitor for next shift
Cement Grinding	Energy optimization required	Monitor for next shift
Packing Plant	8% higher than last week	Investigate equipment load
Utilities	Energy optimization required	Engineering team notified

Quality Deviation Reports – Reference Page 121

During the operational review, the engineering team documented changes in temperature associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Maintenance Work Orders – Reference Page 122

During the operational review, the engineering team documented changes in bearing temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Maintenance Work Orders – Reference Page 123

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased power consumption observed in Raw Mill Fan during routine monitoring.	Dust accumulation	Kiln instability risk	Conduct vibration analysis
Increased pressure observed in Clinker Cooler during routine monitoring.	Bearing wear	Higher energy consumption	Inspect equipment immediately
Increased pressure observed in ID Fan during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Schedule maintenance shutdown
Increased vibration observed in Bucket Elevator during routine monitoring.	Dust accumulation	Higher energy consumption	Schedule maintenance shutdown

Increased motor current observed in ID Fan during routine monitoring.	Process imbalance	Reduced mill throughput	Adjust process parameters

Process Optimization Notes – Reference Page 124

During the operational review, the engineering team documented changes in motor current associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Shutdown and Turnaround Reports – Reference Page 125

During the operational review, the engineering team documented changes in motor current associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Within target range	Investigate equipment load
Raw Mill	8% higher than last week	Possible process fluctuation
Cement Grinding	Within target range	Possible process fluctuation
Packing Plant	Energy optimization required	Engineering team notified
Utilities	Within target range	Investigate equipment load

Process Optimization Notes – Reference Page 126

During the operational review, the engineering team documented changes in feed rate associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased vibration observed in Rotary Kiln during routine monitoring.	Dust accumulation	Kiln instability risk	Schedule maintenance shutdown
Increased power consumption observed in Bag Filter during routine monitoring.	Improper lubrication	Reduced mill throughput	Inspect equipment immediately
Increased vibration observed in Ball Mill during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Inspect equipment immediately
Increased air flow observed in Vertical Roller Mill during routine monitoring.	Dust accumulation	Kiln instability risk	Adjust process parameters

Increased feed rate observed in Rotary Kiln during routine monitoring.	Process imbalance	Kiln instability risk	Schedule maintenance shutdown

Environmental Audit Notes – Reference Page 127

During the operational review, the engineering team documented changes in pressure associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Optimization Notes – Reference Page 128

During the operational review, the engineering team documented changes in feed rate associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Improvement Recommendations – Reference Page 129

During the operational review, the engineering team documented changes in bearing temperature associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased vibration observed in Electrostatic Precipitator during routine monitoring.	Process imbalance	Reduced mill throughput	Inspect equipment immediately
Increased feed rate observed in Raw Mill Fan during routine monitoring.	Bearing wear	Quality fluctuation risk	Conduct vibration analysis
Increased temperature observed in Cement Separator during routine monitoring.	Process imbalance	Reduced mill throughput	Schedule maintenance shutdown
Increased temperature observed in Raw Mill	Bearing wear	Kiln instability risk	Schedule maintenance shutdown

Fan during routine monitoring.			
Increased power consumption observed in Packing Machine during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Conduct vibration analysis

Environmental Audit Notes – Reference Page 130

During the operational review, the engineering team documented changes in vibration associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	5% above baseline	Monitor for next shift
Raw Mill	5% above baseline	Monitor for next shift

Utilities	5% above baseline	Monitor for next shift

Root Cause Analysis Records – Reference Page 146

During the operational review, the engineering team documented changes in temperature associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Improvement Recommendations – Reference Page 147

During the operational review, the engineering team documented changes in motor current associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased vibration observed in Bucket Elevator during routine monitoring.	Improper lubrication	Higher energy consumption	Schedule maintenance shutdown
Increased air flow observed in Ball Mill during routine monitoring.	Bearing wear	Higher energy consumption	Schedule maintenance shutdown
Increased feed rate observed in ID Fan during routine monitoring.	Process imbalance	Higher energy consumption	Schedule maintenance shutdown
Increased pressure observed in Packing Machine during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Adjust process parameters

Increased power consumption observed in Vertical Roller Mill during routine monitoring.	Bearing wear	Higher energy consumption	Inspect equipment immediately

Maintenance Work Orders – Reference Page 148

During the operational review, the engineering team documented changes in feed rate associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Maintenance Work Orders – Reference Page 149

During the operational review, the engineering team documented changes in temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Shutdown and Turnaround Reports – Reference Page 150

During the operational review, the engineering team documented changes in power consumption associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased vibration observed in Limestone Crusher during routine monitoring.	Bearing wear	Kiln instability risk	Schedule maintenance shutdown
Increased temperature observed in Electrostatic Precipitator during routine monitoring.	Improper lubrication	Kiln instability risk	Conduct vibration analysis
Increased motor current observed in Packing Machine during routine monitoring.	Improper lubrication	Higher energy consumption	Adjust process parameters
Increased air flow	Bearing wear	Reduced mill	Schedule

observed in Limestone Crusher during routine monitoring.		throughput	maintenance shutdown
Increased air flow observed in Ball Mill during routine monitoring.	Improper lubrication	Kiln instability risk	Schedule maintenance shutdown

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Within target range	Engineering team notified
Raw Mill	5% above baseline	Possible process fluctuation
Cement Grinding	Within target range	Possible process fluctuation
Packing Plant	5% above baseline	Possible process fluctuation
Utilities	Within target range	Possible process fluctuation

Shutdown and Turnaround Reports – Reference Page 151

During the operational review, the engineering team documented changes in motor current associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 152

During the operational review, the engineering team documented changes in feed rate associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Production Planning Notes – Reference Page 153

During the operational review, the engineering team documented changes in vibration associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased temperature observed in Clinker Cooler during routine monitoring.	Bearing wear	Quality fluctuation risk	Conduct vibration analysis
Increased power consumption observed in Bag Filter during routine monitoring.	Improper lubrication	Kiln instability risk	Inspect equipment immediately
Increased pressure observed in Bag Filter during routine monitoring.	Dust accumulation	Quality fluctuation risk	Conduct vibration analysis
Increased feed rate observed in Vertical Roller Mill during	Dust accumulation	Quality fluctuation risk	Inspect equipment immediately

routine monitoring.

Increased power consumption observed in Limestone Crusher during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Adjust process parameters

Quality Deviation Reports – Reference Page 154

During the operational review, the engineering team documented changes in temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Operational Incident Reports – Reference Page 155

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Within target range	Investigate equipment load
Raw Mill	5% above baseline	Monitor for next shift
Cement Grinding	5% above baseline	Monitor for next shift
Packing Plant	5% above baseline	Monitor for next shift
Utilities	Within target range	Possible process fluctuation

Quality Deviation Reports – Reference Page 156

During the operational review, the engineering team documented changes in pressure associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased temperature observed in Ball Mill during routine monitoring.	Dust accumulation	Higher energy consumption	Adjust process parameters
Increased power consumption observed in Limestone Crusher during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Inspect equipment immediately
Increased bearing temperature observed in Electrostatic Precipitator during routine monitoring.	Bearing wear	Kiln instability risk	Adjust process parameters

Operational Incident Reports – Reference Page 175

During the operational review, the engineering team documented changes in bearing temperature associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Energy optimization required	Possible process fluctuation
Raw Mill	8% higher than last week	Investigate equipment load
Cement Grinding	8% higher than last week	Possible process fluctuation
Packing Plant	5% above baseline	Monitor for next shift
Utilities	5% above baseline	Possible process fluctuation

Shutdown and Turnaround Reports – Reference Page 176

During the operational review, the engineering team documented changes in air flow associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Shutdown and Turnaround Reports – Reference Page 177

During the operational review, the engineering team documented changes in feed rate associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Bucket Elevator during routine monitoring.	Improper lubrication	Higher energy consumption	Schedule maintenance shutdown
Increased air flow observed in Clinker Cooler during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Schedule maintenance shutdown
Increased feed rate observed in Bag Filter during routine monitoring.	Process imbalance	Reduced mill throughput	Inspect equipment immediately
Increased vibration observed in Packing Machine during routine monitoring.	Process imbalance	Reduced mill throughput	Inspect equipment immediately

Increased air flow observed in Ball Mill during routine monitoring.	Improper lubrication	Kiln instability risk	Inspect equipment immediately

Energy Consumption Reports – Reference Page 178

During the operational review, the engineering team documented changes in bearing temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Production Planning Notes – Reference Page 179

During the operational review, the engineering team documented changes in vibration associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 180

During the operational review, the engineering team documented changes in feed rate associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Packing Machine during routine monitoring.	Dust accumulation	Higher energy consumption	Adjust process parameters
Increased motor current observed in Clinker Cooler during routine monitoring.	Process imbalance	Higher energy consumption	Adjust process parameters
Increased feed rate observed in Rotary Kiln during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Inspect equipment immediately
Increased air flow observed in Bucket Elevator during routine monitoring.	Process imbalance	Quality fluctuation risk	Conduct vibration analysis
Increased bearing	Operator parameter	Quality fluctuation	Adjust process

temperature observed in Electrostatic Precipitator during routine monitoring.	adjustment	risk	parameters

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Energy optimization required	Monitor for next shift
Raw Mill	Energy optimization required	Monitor for next shift
Cement Grinding	Energy optimization required	Investigate equipment load
Packing Plant	Energy optimization required	Engineering team notified
Utilities	8% higher than last week	Possible process fluctuation

Shutdown and Turnaround Reports – Reference Page 181

During the operational review, the engineering team documented changes in pressure associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Kiln Performance Analysis – Reference Page 182

During the operational review, the engineering team documented changes in temperature associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Investigation Reports – Reference Page 183

During the operational review, the engineering team documented changes in air flow associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased temperature observed in ID Fan during routine monitoring.	Dust accumulation	Higher energy consumption	Schedule maintenance shutdown
Increased power consumption observed in Raw Mill Fan during routine monitoring.	Dust accumulation	Kiln instability risk	Schedule maintenance shutdown
Increased air flow observed in Cement Separator during routine monitoring.	Process imbalance	Quality fluctuation risk	Inspect equipment immediately
Increased temperature observed in Rotary	Dust accumulation	Kiln instability risk	Adjust process parameters

Kiln during routine monitoring.			
Increased vibration observed in Limestone Crusher during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Conduct vibration analysis

Environmental Audit Notes – Reference Page 184

During the operational review, the engineering team documented changes in feed rate associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Consumption Reports – Reference Page 185

During the operational review, the engineering team documented changes in air flow associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	5% above baseline	Possible process fluctuation
Raw Mill	Within target range	Engineering team notified
Cement Grinding	Energy optimization required	Investigate equipment load
Packing Plant	Energy optimization required	Engineering team notified
Utilities	8% higher than last week	Monitor for next shift

Production Planning Notes – Reference Page 186

During the operational review, the engineering team documented changes in power consumption associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action

During the operational review, the engineering team documented changes in pressure associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased feed rate observed in Clinker Cooler during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Inspect equipment immediately
Increased motor current observed in Raw Mill Fan during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Schedule maintenance shutdown
Increased vibration observed in Rotary Kiln during routine monitoring.	Bearing wear	Reduced mill throughput	Adjust process parameters
Increased power consumption observed in Rotary Kiln during routine monitoring.	Dust accumulation	Higher energy consumption	Inspect equipment immediately

Increased air flow observed in Vertical Roller Mill during routine monitoring.	Bearing wear	Higher energy consumption	Conduct vibration analysis

Production Planning Notes – Reference Page 205

During the operational review, the engineering team documented changes in bearing temperature associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	8% higher than last week	Investigate equipment load
Raw Mill	5% above baseline	Possible process fluctuation
Cement Grinding	5% above baseline	Possible process fluctuation
Packing Plant	8% higher than last week	Engineering team notified
Utilities	Energy optimization required	Investigate equipment load

Operational Incident Reports – Reference Page 206

During the operational review, the engineering team documented changes in feed rate associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Maintenance Work Orders – Reference Page 207

During the operational review, the engineering team documented changes in air flow associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased temperature observed in Clinker Cooler during routine monitoring.	Bearing wear	Kiln instability risk	Inspect equipment immediately
Increased vibration observed in Vertical Roller Mill during routine monitoring.	Dust accumulation	Reduced mill throughput	Schedule maintenance shutdown
Increased feed rate observed in Packing Machine during routine monitoring.	Bearing wear	Kiln instability risk	Conduct vibration analysis
Increased feed rate observed in Cement Separator during routine monitoring.	Bearing wear	Reduced mill throughput	Conduct vibration analysis

Increased motor current observed in Cement Separator during routine monitoring.	Bearing wear	Higher energy consumption	Inspect equipment immediately

Operational Incident Reports – Reference Page 208

During the operational review, the engineering team documented changes in feed rate associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Optimization Notes – Reference Page 209

During the operational review, the engineering team documented changes in air flow associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Kiln Performance Analysis – Reference Page 210

During the operational review, the engineering team documented changes in power consumption associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased pressure observed in Bucket Elevator during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Schedule maintenance shutdown
Increased power consumption observed in Packing Machine during routine monitoring.	Process imbalance	Quality fluctuation risk	Conduct vibration analysis
Increased temperature observed in Raw Mill Fan during routine monitoring.	Process imbalance	Reduced mill throughput	Inspect equipment immediately
Increased motor current observed in Vertical Roller Mill	Bearing wear	Quality fluctuation risk	Conduct vibration analysis

during routine monitoring.			
Increased power consumption observed in Electrostatic Precipitator during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Conduct vibration analysis

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Energy optimization required	Monitor for next shift
Raw Mill	5% above baseline	Possible process fluctuation
Cement Grinding	8% higher than last week	Engineering team notified
Packing Plant	5% above baseline	Monitor for next shift
Utilities	5% above baseline	Possible process fluctuation

Shutdown and Turnaround Reports – Reference Page 211

During the operational review, the engineering team documented changes in vibration associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Kiln Performance Analysis – Reference Page 212

During the operational review, the engineering team documented changes in motor current associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Optimization Notes – Reference Page 213

During the operational review, the engineering team documented changes in motor current associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased power consumption observed in ID Fan during routine monitoring.	Process imbalance	Kiln instability risk	Inspect equipment immediately
Increased air flow observed in Rotary Kiln during routine monitoring.	Process imbalance	Quality fluctuation risk	Schedule maintenance shutdown
Increased temperature observed in Cement Separator during routine monitoring.	Bearing wear	Quality fluctuation risk	Schedule maintenance shutdown
Increased feed rate observed in Cement Separator during	Process imbalance	Higher energy consumption	Conduct vibration analysis

routine monitoring.

Increased power consumption observed in Bucket Elevator during routine monitoring.	Process imbalance	Higher energy consumption	Schedule maintenance shutdown

Energy Consumption Reports – Reference Page 214

During the operational review, the engineering team documented changes in feed rate associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Equipment Failure Case Studies – Reference Page 215

During the operational review, the engineering team documented changes in bearing temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Within target range	Engineering team notified
Raw Mill	5% above baseline	Monitor for next shift
Cement Grinding	Within target range	Investigate equipment load
Packing Plant	8% higher than last week	Possible process fluctuation
Utilities	8% higher than last week	Monitor for next shift

Process Improvement Recommendations – Reference Page 216

During the operational review, the engineering team documented changes in bearing temperature associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased pressure observed in Packing Machine during routine monitoring.	Improper lubrication	Reduced mill throughput	Conduct vibration analysis
Increased feed rate observed in Bag Filter during routine monitoring.	Dust accumulation	Quality fluctuation risk	Schedule maintenance shutdown
Increased bearing temperature observed in Limestone Crusher during routine monitoring.	Improper lubrication	Higher energy consumption	Inspect equipment immediately
Increased feed rate observed in Vertical Roller Mill during	Process imbalance	Kiln instability risk	Conduct vibration analysis

routine monitoring.			
Increased pressure observed in Packing Machine during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Inspect equipment immediately

Kiln Performance Analysis – Reference Page 217

During the operational review, the engineering team documented changes in air flow associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 218

During the operational review, the engineering team documented changes in feed rate associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Root Cause Analysis Records – Reference Page 219

During the operational review, the engineering team documented changes in feed rate associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Environmental Audit Notes – Reference Page 233

During the operational review, the engineering team documented changes in bearing temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Kiln Performance Analysis – Reference Page 234

During the operational review, the engineering team documented changes in air flow associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Electrostatic Precipitator during routine monitoring.	Operator parameter adjustment	Kiln instability risk	Schedule maintenance shutdown
Increased air flow observed in Limestone Crusher during routine monitoring.	Bearing wear	Quality fluctuation risk	Conduct vibration analysis
Increased air flow observed in Vertical Roller Mill during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Adjust process parameters
Increased motor current observed in Vertical Roller Mill	Dust accumulation	Kiln instability risk	Schedule maintenance shutdown

during routine monitoring.			
Increased power consumption observed in Ball Mill during routine monitoring.	Dust accumulation	Quality fluctuation risk	Conduct vibration analysis

Shutdown and Turnaround Reports – Reference Page 235

During the operational review, the engineering team documented changes in temperature associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Within target range	Possible process fluctuation
Raw Mill	5% above baseline	Monitor for next shift
Cement Grinding	Energy optimization required	Investigate equipment load
Packing Plant	Within target range	Investigate equipment load
Utilities	8% higher than last week	Monitor for next shift

Quality Deviation Reports – Reference Page 236

During the operational review, the engineering team documented changes in bearing temperature associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Operational Incident Reports – Reference Page 237

During the operational review, the engineering team documented changes in bearing temperature associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased temperature observed in ID Fan during routine monitoring.	Process imbalance	Kiln instability risk	Adjust process parameters
Increased vibration observed in Cement Separator during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Schedule maintenance shutdown
Increased feed rate observed in Bag Filter during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Adjust process parameters
Increased power consumption observed in Raw Mill Fan during routine	Dust accumulation	Quality fluctuation risk	Conduct vibration analysis

monitoring.			
Increased pressure observed in Cement Separator during routine monitoring.	Bearing wear	Kiln instability risk	Adjust process parameters

Shutdown and Turnaround Reports – Reference Page 238

During the operational review, the engineering team documented changes in motor current associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Clinker Cooler. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Ball Mill during routine monitoring.	Dust accumulation	Higher energy consumption	Conduct vibration analysis
Increased power consumption observed in Bucket Elevator during routine monitoring.	Process imbalance	Kiln instability risk	Adjust process parameters
Increased vibration observed in Raw Mill Fan during routine monitoring.	Improper lubrication	Kiln instability risk	Adjust process parameters
Increased motor current observed in Limestone Crusher during routine	Dust accumulation	Quality fluctuation risk	Schedule maintenance shutdown

monitoring.

Increased air flow observed in Ball Mill during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Inspect equipment immediately

Energy Consumption Reports – Reference Page 262

During the operational review, the engineering team documented changes in bearing temperature associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Operational Incident Reports – Reference Page 263

During the operational review, the engineering team documented changes in feed rate associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Shutdown and Turnaround Reports – Reference Page 264

During the operational review, the engineering team documented changes in power consumption associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Rotary Kiln during routine monitoring.	Improper lubrication	Reduced mill throughput	Adjust process parameters
Increased air flow observed in Bag Filter during routine monitoring.	Dust accumulation	Kiln instability risk	Conduct vibration analysis
Increased feed rate observed in Raw Mill Fan during routine monitoring.	Dust accumulation	Reduced mill throughput	Conduct vibration analysis
Increased motor current observed in Packing Machine during routine monitoring.	Process imbalance	Reduced mill throughput	Adjust process parameters

Increased vibration observed in Packing Machine during routine monitoring.	Bearing wear	Quality fluctuation risk	Adjust process parameters

Equipment Failure Case Studies – Reference Page 265

During the operational review, the engineering team documented changes in motor current associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	5% above baseline	Investigate equipment load
Raw Mill	5% above baseline	Possible process fluctuation
Cement Grinding	Within target range	Investigate equipment load
Packing Plant	5% above baseline	Possible process fluctuation
Utilities	Energy optimization required	Investigate equipment load

Engineering Investigation Reports – Reference Page 266

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Optimization Notes – Reference Page 267

During the operational review, the engineering team documented changes in power consumption associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased temperature observed in Rotary Kiln during routine monitoring.	Improper lubrication	Higher energy consumption	Adjust process parameters
Increased power consumption observed in Ball Mill during routine monitoring.	Improper lubrication	Higher energy consumption	Conduct vibration analysis
Increased vibration observed in Raw Mill Fan during routine monitoring.	Improper lubrication	Reduced mill throughput	Schedule maintenance shutdown
Increased bearing temperature observed in Packing	Operator parameter adjustment	Reduced mill throughput	Adjust process parameters

Machine during routine monitoring.			
Increased feed rate observed in Clinker Cooler during routine monitoring.	Improper lubrication	Reduced mill throughput	Conduct vibration analysis

Operational Incident Reports – Reference Page 268

During the operational review, the engineering team documented changes in vibration associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Kiln Performance Analysis – Reference Page 269

During the operational review, the engineering team documented changes in pressure associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Kiln Performance Analysis – Reference Page 270

During the operational review, the engineering team documented changes in air flow associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased feed rate observed in Electrostatic Precipitator during routine monitoring.	Bearing wear	Quality fluctuation risk	Inspect equipment immediately
Increased power consumption observed in Clinker Cooler during routine monitoring.	Bearing wear	Kiln instability risk	Adjust process parameters
Increased feed rate observed in Rotary Kiln during routine monitoring.	Dust accumulation	Higher energy consumption	Adjust process parameters
Increased feed rate observed in Cement Separator during	Improper lubrication	Reduced mill throughput	Schedule maintenance shutdown

routine monitoring.			
Increased pressure observed in Raw Mill Fan during routine monitoring.	Process imbalance	Kiln instability risk	Conduct vibration analysis

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Within target range	Monitor for next shift
Raw Mill	Within target range	Monitor for next shift
Cement Grinding	5% above baseline	Investigate equipment load
Packing Plant	Energy optimization required	Possible process fluctuation
Utilities	Within target range	Engineering team notified

Environmental Audit Notes – Reference Page 271

During the operational review, the engineering team documented changes in feed rate associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Environmental Audit Notes – Reference Page 272

During the operational review, the engineering team documented changes in air flow associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Department	Energy Consumption Indicator	Remarks
Kiln Section	Within target range	Investigate equipment load
Raw Mill	8% higher than last week	Investigate equipment load
Cement Grinding	Energy optimization required	Investigate equipment load
Packing Plant	Within target range	Investigate equipment load
Utilities	Within target range	Investigate equipment load

Environmental Audit Notes – Reference Page 291

During the operational review, the engineering team documented changes in power consumption associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased pressure observed in Ball Mill during routine monitoring.	Dust accumulation	Higher energy consumption	Inspect equipment immediately
Increased power consumption observed in Ball Mill during routine monitoring.	Bearing wear	Higher energy consumption	Inspect equipment immediately
Increased pressure observed in Raw Mill Fan during routine monitoring.	Improper lubrication	Quality fluctuation risk	Schedule maintenance shutdown
Increased air flow observed in Ball Mill during routine monitoring.	Process imbalance	Reduced mill throughput	Adjust process parameters

Increased feed rate observed in Electrostatic Precipitator during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Schedule maintenance shutdown

Kiln Performance Analysis – Reference Page 292

During the operational review, the engineering team documented changes in feed rate associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Environmental Audit Notes – Reference Page 293

During the operational review, the engineering team documented changes in air flow associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Improvement Recommendations – Reference Page 294

During the operational review, the engineering team documented changes in pressure associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased motor current observed in Bag Filter during routine monitoring.	Improper lubrication	Higher energy consumption	Adjust process parameters
Increased motor current observed in Ball Mill during routine monitoring.	Dust accumulation	Quality fluctuation risk	Adjust process parameters
Increased feed rate observed in Clinker Cooler during routine monitoring.	Bearing wear	Kiln instability risk	Inspect equipment immediately
Increased power consumption observed in Rotary Kiln during routine monitoring.	Improper lubrication	Higher energy consumption	Inspect equipment immediately

Increased vibration observed in Ball Mill during routine monitoring.	Improper lubrication	Higher energy consumption	Inspect equipment immediately

Process Optimization Notes – Reference Page 295

During the operational review, the engineering team documented changes in pressure associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Energy optimization required	Engineering team notified
Raw Mill	Energy optimization required	Monitor for next shift
Cement Grinding	Energy optimization required	Monitor for next shift
Packing Plant	5% above baseline	Possible process fluctuation
Utilities	5% above baseline	Engineering team notified

Shutdown and Turnaround Reports – Reference Page 296

During the operational review, the engineering team documented changes in pressure associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Consumption Reports – Reference Page 297

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased pressure observed in Ball Mill during routine monitoring.	Dust accumulation	Kiln instability risk	Adjust process parameters
Increased power consumption observed in Bucket Elevator during routine monitoring.	Improper lubrication	Reduced mill throughput	Adjust process parameters
Increased motor current observed in Vertical Roller Mill during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Adjust process parameters
Increased bearing temperature observed in Ball Mill	Improper lubrication	Reduced mill throughput	Conduct vibration analysis

during routine monitoring.			
Increased air flow observed in Bucket Elevator during routine monitoring.	Operator parameter adjustment	Higher energy consumption	Conduct vibration analysis

Maintenance Work Orders – Reference Page 298

During the operational review, the engineering team documented changes in pressure associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Improvement Recommendations – Reference Page 299

During the operational review, the engineering team documented changes in pressure associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Equipment Failure Case Studies – Reference Page 300

During the operational review, the engineering team documented changes in vibration associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased vibration observed in Bag Filter during routine monitoring.	Process imbalance	Kiln instability risk	Conduct vibration analysis
Increased pressure observed in Raw Mill Fan during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Adjust process parameters
Increased temperature observed in Limestone Crusher during routine monitoring.	Process imbalance	Reduced mill throughput	Conduct vibration analysis
Increased bearing temperature observed in ID Fan	Dust accumulation	Kiln instability risk	Adjust process parameters

during routine monitoring.			
Increased motor current observed in Rotary Kiln during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Conduct vibration analysis

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Within target range	Investigate equipment load
Raw Mill	5% above baseline	Engineering team notified
Cement Grinding	8% higher than last week	Monitor for next shift
Packing Plant	Within target range	Engineering team notified
Utilities	8% higher than last week	Investigate equipment load

Equipment Failure Case Studies – Reference Page 301

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Improvement Recommendations – Reference Page 302

During the operational review, the engineering team documented changes in air flow associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Consumption Reports – Reference Page 303

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased power consumption observed in Rotary Kiln during routine monitoring.	Improper lubrication	Kiln instability risk	Adjust process parameters
Increased power consumption observed in Clinker Cooler during routine monitoring.	Improper lubrication	Reduced mill throughput	Adjust process parameters
Increased air flow observed in Raw Mill Fan during routine monitoring.	Process imbalance	Reduced mill throughput	Schedule maintenance shutdown
Increased pressure observed in Bag Filter during routine	Improper lubrication	Higher energy consumption	Schedule maintenance shutdown

monitoring.

Increased bearing temperature observed in Bucket Elevator during routine monitoring.	Operator parameter adjustment	Reduced mill throughput	Conduct vibration analysis

Equipment Failure Case Studies – Reference Page 304

During the operational review, the engineering team documented changes in temperature associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Shutdown and Turnaround Reports – Reference Page 305

During the operational review, the engineering team documented changes in pressure associated with the ID Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks

Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Rotary Kiln. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Environmental Audit Notes – Reference Page 320

During the operational review, the engineering team documented changes in vibration associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	5% above baseline	Monitor for next shift
Raw Mill	Energy optimization required	Possible process fluctuation
Cement Grinding	Energy optimization required	Engineering team notified
Packing Plant	Energy optimization required	Monitor for next shift
Utilities	8% higher than last week	Possible process fluctuation

Process Improvement Recommendations – Reference Page 321

During the operational review, the engineering team documented changes in air flow associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased power consumption observed in Vertical Roller Mill during routine monitoring.	Process imbalance	Higher energy consumption	Adjust process parameters
Increased air flow observed in Electrostatic Precipitator during routine monitoring.	Bearing wear	Higher energy consumption	Inspect equipment immediately
Increased pressure observed in Clinker Cooler during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Inspect equipment immediately
Increased air flow observed in Rotary Kiln during routine	Process imbalance	Kiln instability risk	Adjust process parameters

monitoring.			
Increased feed rate observed in Rotary Kiln during routine monitoring.	Improper lubrication	Higher energy consumption	Inspect equipment immediately

Root Cause Analysis Records – Reference Page 322

During the operational review, the engineering team documented changes in feed rate associated with the Bag Filter. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Maintenance Work Orders – Reference Page 323

During the operational review, the engineering team documented changes in motor current associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Raw Mill Fan. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Operational Incident Reports – Reference Page 324

During the operational review, the engineering team documented changes in power consumption associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased vibration observed in Packing Machine during routine monitoring.	Bearing wear	Higher energy consumption	Conduct vibration analysis
Increased air flow observed in Clinker Cooler during routine monitoring.	Process imbalance	Quality fluctuation risk	Conduct vibration analysis
Increased bearing temperature observed in Clinker Cooler during routine monitoring.	Improper lubrication	Reduced mill throughput	Schedule maintenance shutdown
Increased pressure observed in Bag Filter during routine monitoring.	Dust accumulation	Kiln instability risk	Inspect equipment immediately

Increased bearing temperature observed in Bag Filter during routine monitoring.	Operator parameter adjustment	Quality fluctuation risk	Adjust process parameters

Process Improvement Recommendations – Reference Page 325

During the operational review, the engineering team documented changes in feed rate associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Clinker Cooler. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	5% above baseline	Investigate equipment load
Raw Mill	Energy optimization required	Monitor for next shift
Cement Grinding	Within target range	Possible process fluctuation
Packing Plant	Within target range	Possible process fluctuation
Utilities	Energy optimization required	Possible process fluctuation

Root Cause Analysis Records – Reference Page 326

During the operational review, the engineering team documented changes in vibration associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Process Optimization Notes – Reference Page 327

During the operational review, the engineering team documented changes in power consumption associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased air flow observed in Electrostatic Precipitator during routine monitoring.	Improper lubrication	Kiln instability risk	Inspect equipment immediately
Increased feed rate observed in Electrostatic Precipitator during routine monitoring.	Bearing wear	Reduced mill throughput	Inspect equipment immediately
Increased pressure observed in Raw Mill Fan during routine monitoring.	Dust accumulation	Higher energy consumption	Schedule maintenance shutdown
Increased power consumption observed in Bucket	Improper lubrication	Reduced mill throughput	Schedule maintenance shutdown

Elevator during routine monitoring.			
Increased pressure observed in Vertical Roller Mill during routine monitoring.	Process imbalance	Quality fluctuation risk	Schedule maintenance shutdown

Shutdown and Turnaround Reports – Reference Page 328

During the operational review, the engineering team documented changes in air flow associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in bearing temperature associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Consumption Reports – Reference Page 329

During the operational review, the engineering team documented changes in vibration associated with the Vertical Roller Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in pressure associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 330

During the operational review, the engineering team documented changes in power consumption associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in motor current associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Bucket Elevator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased pressure observed in Ball Mill during routine monitoring.	Improper lubrication	Higher energy consumption	Adjust process parameters
Increased air flow observed in Cement Separator during routine monitoring.	Bearing wear	Reduced mill throughput	Conduct vibration analysis
Increased pressure observed in Bag Filter during routine monitoring.	Dust accumulation	Kiln instability risk	Adjust process parameters
Increased bearing temperature observed in Bucket Elevator during routine monitoring.	Improper lubrication	Higher energy consumption	Inspect equipment immediately

Increased air flow observed in Clinker Cooler during routine monitoring.	Process imbalance	Quality fluctuation risk	Adjust process parameters

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	Energy optimization required	Investigate equipment load
Raw Mill	Within target range	Investigate equipment load

Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in air flow associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Engineering Analysis Table

Observation	Possible Cause	Impact on Production	Recommended Action
Increased motor current observed in Ball Mill during routine monitoring.	Process imbalance	Quality fluctuation risk	Conduct vibration analysis
Increased air flow observed in Electrostatic Precipitator during routine monitoring.	Improper lubrication	Higher energy consumption	Adjust process parameters
Increased air flow observed in Raw Mill Fan during routine monitoring.	Process imbalance	Higher energy consumption	Schedule maintenance shutdown
Increased bearing temperature observed in Vertical Roller Mill during	Process imbalance	Kiln instability risk	Inspect equipment immediately

routine monitoring.			
Increased air flow observed in Limestone Crusher during routine monitoring.	Process imbalance	Kiln instability risk	Schedule maintenance shutdown

Process Improvement Recommendations – Reference Page 349

During the operational review, the engineering team documented changes in air flow associated with the Electrostatic Precipitator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in power consumption associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in vibration associated with the Cement Separator. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Quality Deviation Reports – Reference Page 350

During the operational review, the engineering team documented changes in temperature associated with the Limestone Crusher. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in temperature associated with the Packing Machine. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

During the operational review, the engineering team documented changes in feed rate associated with the Ball Mill. Historical logs and maintenance records were examined to determine whether the variation was caused by process fluctuation, equipment wear, or energy efficiency issues. Cross-referencing production data and maintenance work orders is recommended before implementing corrective measures.

Energy Monitoring Log

Department	Energy Consumption Indicator	Remarks
Kiln Section	5% above baseline	Possible process fluctuation
Raw Mill	Energy optimization required	Possible process fluctuation
Cement Grinding	Energy optimization required	Investigate equipment load
Packing Plant	5% above baseline	Investigate equipment load
Utilities	8% higher than last week	Monitor for next shift
